3.1.2. Bellman-Ford algorithm. The Bellman-Ford algorithm solves the single-source shortest paths
problem in  $O(|V||E|)$  time. It is slower than Dijkstra’s algorithm, but it works on graphs with
negative edges and has the ability to detect negative cycles, neither of which Dijkstra’s algorithm can
do.

3.11. All Pairs Maximum Flow.

3.11.1. *Gomory-Hu Tree.* An implementation of the Gomory-Hu Tree. The spanning tree is constructed using Gusfield’s algorithm in $O(|V|^2)$ plus $|V| - 1$ times the time it takes to calculate the maximum flow. If Dinic’s algorithm is used to calculate the max flow, the running time is $O(|V|^3|E|)$. NOTE: Not sure if it works correctly with disconnected graphs.

3.16. **Maximum Density Subgraph.** Given (weighted) undirected graph G . Binary search density. If g is current density, construct flow network: (S, u, m) , $(u, T, m + 2g - d_u)$, $(u, v, 1)$, where m is a large constant (larger than sum of edge weights). Run floating-point max-flow. If minimum cut has empty S -component, then maximum density is smaller than g , otherwise it’s larger. Distance between valid densities is at least $1/(n(n - 1))$. Edge case when density is 0. This also works for weighted graphs by replacing d_u by the weighted degree, and doing more iterations (if weights are not integers).

3.17. **Maximum-Weight Closure.** Given a vertex-weighted directed graph G . Turn the graph into a flow network, adding weight ∞ to each edge. Add vertices S, T . For each vertex v of weight w , add edge (S, v, w) if $w \geq 0$, or edge $(v, T, -w)$ if $w < 0$. Sum of positive weights minus minimum $S - T$ cut is the answer. Vertices reachable from S are in the closure. The maximum-weight closure is the same as the complement of the minimum-weight closure on the graph with edges reversed.

3.18. **Maximum Weighted Independent Set in a Bipartite Graph.** This is the same as the minimum weighted vertex cover. Solve this by constructing a flow network with edges $(S, u, w(u))$ for $u \in L$, $(v, T, w(v))$ for $v \in R$ and (u, v, ∞) for $(u, v) \in E$. The minimum S, T -cut is the answer. Vertices adjacent to a cut edge are in the vertex cover.

4. STRINGS

4.1. **The Knuth-Morris-Pratt algorithm.** An implementation of the Knuth-Morris-Pratt algorithm. Runs in $O(n + m)$ time, where n and m are the lengths of the string and the pattern.

```
int* compute_pi(const string &t) {-----// a2
----int m = t.size();-----// 8b
----int *pit = new int[m + 1];-----// 8e
----if (0 <= m) pit[0] = 0;-----// 42
----if (1 <= m) pit[1] = 0;-----// 34
----rep(i,2,m+1) {-----// 0f
```

```
-----for (int j = pit[i - 1]; ; j = pit[j]) {-----// b5
-----if (t[j] == t[i - 1]) { pit[i] = j + 1; break; }-----// 21
-----if (j == 0) { pit[i] = 0; break; }-----// 95
-----}-----// c9
-----}-----// eb
-----return pit; }-----// e8
int string_match(const string &s, const string &t) {-----// 9e
-----int n = s.size(), m = t.size();-----// 92
-----int *pit = compute_pi(t);-----// 72
-----for (int i = 0, j = 0; i < n; ) {-----// 27
-----if (s[i] == t[j]) {-----// 73
-----i++; j++;-----// 7e
-----if (j == m) {-----// de
-----return i - m;-----// e9
-----// or j = pit[j];-----// ce
-----}-----// 85
-----}-----// 35
-----else if (j > 0) j = pit[j];-----// 43
-----else i++; }-----// b8
-----delete[] pit; return -1; }-----// e3
```

4.2. **The Z algorithm.** Given a string S , $Z_i(S)$ is the longest substring of S starting at i that is also a prefix of S . The Z algorithm computes these Z values in $O(n)$ time, where $n = |S|$. Z values can, for example, be used to find all occurrences of a pattern P in a string T in linear time. This is accomplished by computing Z values of $S = PT$, and looking for all i such that $Z_i \geq |P|$.

```
int* z_values(const string &s) {-----// 4d
-----int n = size(s);-----// 97
-----int* z = new int[n];-----// c4
-----int l = 0, r = 0;-----// 1c
-----z[0] = n;-----// 98
-----rep(i,1,n) {-----// b2
-----z[i] = 0;-----// 4c
-----if (i > r) {-----// 6d
-----l = r = i;-----// 24
-----while (r < n && s[r - l] == s[r]) r++;-----// 68
-----z[i] = r - l; r--;-----// 07
-----} else if (z[i - l] < r - i + 1) z[i] = z[i - l];-----// 6f
-----else {-----// a8
-----l = i;-----// 55
-----while (r < n && s[r - l] == s[r]) r++;-----// 2c
-----z[i] = r - l; r--; } }-----// 13
-----return z;-----// 78
}-----// 16
```

4.3. **Trie.** A Trie class.

5.4. **Euclidean algorithm.** The Euclidean algorithm computes the greatest common divisor of two integers a, b .

```
int gcd(int a, int b) { return b == 0 ? a : gcd(b, a % b); }-----// d9
```

The extended Euclidean algorithm computes the greatest common divisor d of two integers a, b and also finds two integers x, y such that $a \times x + b \times y = d$.

```

5.10. Modular Exponentiation. A function to perform fast modular exponentiation.

```
template <class T>-----// 82
T mod_pow(T b, T e, T m) {-----// aa
---T res = T(1);-----// 85
---while (e) {-----// b7
-----if (e & T(1)) res = smod(res * b, m);-----// 6d
-----b = smod(b * b, m), e >>= T(1); }-----// 12
---return res;-----// c6
}------// 30
```

5.11. **Modular Multiplicative Inverse.** A function to find a modular multiplicative inverse. Alternatively use `mod_pow(a,m-2,m)` when m is prime.

```
#include "egcd.cpp"-----// 55
-----// e8
int mod_inv(int a, int m) {-----// 49
---int x, y, d = egcd(a, m, x, y);-----// 3e
---if (d != 1) return -1;-----// 20
---return x < 0 ? x + m : x;-----// 3c
}-----// 69
```

A sieve version:

```
vi inv_sieve(int n, int p) {-----// 40
---vi inv(n,1);-----// d7
---rep(i,2,n) inv[i] = (p - (ll)(p/i) * inv[p%i] % p) % p;-----// fe
---return inv; }-----// 14
```

5.12. **Primitive Root.**

```
#include "mod_pow.cpp"-----// c7
ll primitive_root(ll m) {-----// 8a
---vector<ll> div;-----// f2
---for (ll i = 1; i*i <= m-1; i++) {-----// ca

-----if (ok) return x; }-----// 5d
---return -1; }-----// 23
```

5.13. **Chinese Remainder Theorem.** An implementation of the Chinese Remainder Theorem.

```
#include "egcd.cpp"-----// 55
int crt(const vi& as, const vi& ns) {-----// c3
---int cnt = size(as), N = 1, x = 0, r, s, l;-----// 55

---rep(i,0,cnt) egcd(ns[i], l = N/ns[i], r, s), x += as[i] * s * l;-----// 21
---return smod(x, N); }-----// d3
```

5.14. **Linear Congruence Solver.** A function that returns all solutions to $ax \equiv b \pmod n$, modulo n .

```
#include "egcd.cpp"-----// 55
vi linear_congruence(int a, int b, int n) {-----// c8
---int x, y, d = egcd(a, n, x, y);-----// 7a
---vi res;-----// f5
---if (b % d != 0) return res;-----// 30
---int x0 = smod(b / d * x, n);-----// cb
---rep(k,0,d) res.push_back(smod(x0 + k * n / d, n));-----// 17
---return res;-----// 90
}-----// 66
```

5.15. **Tonelli-Shanks algorithm.** Given prime p and integer $1 \leq n < p$, returns the square root r of n modulo p . There is also another solution given by $-r$ modulo p .

```
#include "mod_pow.cpp"-----// c7
ll legendre(ll a, ll p) {-----// 27
---if (a % p == 0) return 0;-----// 29
---if (p == 2) return 1;-----// 9a
---return mod_pow(a, (p-1)/2, p) == 1 ? 1 : -1; }-----// 65
ll tonelli_shanks(ll n, ll p) {-----// e0
---assert(legendre(n,p) == 1);-----// 46

-----c = (ll)b * b % p;-----// 31
-----m = i; }-----// b2
---return r; }-----// 48
```

5.16. **Numeric Integration.** Numeric integration using Simpson's rule.

```
double integrate(double (*f)(double), double a, double b,-----// 76
-----double delta = 1e-6) {-----// c0
---if (abs(a - b) < delta)-----// 38
-----return (b-a)/8 *-----// 56

---return integrate(f, a,-----// 64
----- (a+b)/2, delta) + integrate(f, (a+b)/2, b, delta);-----// 0c
}-----// 4b
```

5.17. **Fast Fourier Transform.** The Cooley-Tukey algorithm for quickly computing the discrete Fourier transform. The `fft` function only supports powers of twos. The `czf` function implements the Chirp Z-transform and supports any size, but is slightly slower.

```
#include <complex>-----// 8e

```

6.6. **Line Segment Intersection.** Computes the intersection between two line segments.

```
#include "lines.cpp"-----// d3
bool line_segment_intersect(L(a, b), L(c, d), point &A, point &B) {-----// f3
    if (abs(a - b) < EPS && abs(c - d) < EPS) {-----// 1c

```

6.7. **Great-Circle Distance.** Computes the distance between two points (given as latitude/longitude coordinates) on a sphere of radius r .

```
double gc_distance(double pLat, double pLong,-----// 7b
    double qLat, double qLong, double r) {-----// a4

}-----// 60
-----// 3f
```

6.8. **Triangle Circumcenter.** Returns the unique point that is the same distance from all three points. It is also the center of the unique circle that goes through all three points.

```
#include "primitives.cpp"-----// e0
point circumcenter(point a, point b, point c) {-----// 76

6.13. **Formulas.** Let $a = (a_x, a_y)$ and $b = (b_x, b_y)$ be two-dimensional vectors.

- $a \cdot b = |a||b| \cos \theta$, where θ is the angle between a and b .
- $a \times b = |a||b| \sin \theta$, where θ is the signed angle between a and b .
- $a \times b$ is equal to the area of the parallelogram with two of its sides formed by a and b . Half of that is the area of the triangle formed by a and b .
- **Euler’s formula:** $V - E + F = 2$
- Side lengths a, b, c can form a triangle iff. $a + b > c$, $b + c > a$ and $a + c > b$.
- Sum of internal angles of a regular convex n -gon is $(n - 2)\pi$.
- **Law of sines:** $\frac{a}{\sin A} = \frac{b}{\sin B} = \frac{c}{\sin C}$
- **Law of cosines:** $b^2 = a^2 + c^2 - 2ac \cos B$

- Internal tangents of circles $(c_1, r_1), (c_2, r_2)$ intersect at $(c_1r_2 + c_2r_1)/(r_1 + r_2)$, external intersect at $(c_1r_2 - c_2r_1)/(r_1 + r_2)$.

----if ((x&7) - 1) return false;-----// 1f
----ll r = sqrt(x);-----// 21
----return r*r == x; }-----// 2a
```

7.11. **Fast Input Reading.** If input or output is huge, sometimes it is beneficial to optimize the input reading/output writing. This can be achieved by reading all input in at once (using fread), and then parsing it manually. Output can also be stored in an output buffer and then dumped once in the end (using fwrite). A simpler, but still effective, way to achieve speed is to use the following input reading method.

```
void readn(register int *n) {-----// dc
----int sign = 1;-----// 32
----register char c;-----// a5
----*n = 0;-----// 35
----while((c = getc_unlocked(stdin)) != '\n') {-----// f3
-----switch(c) {-----// 0c
-----case '-': sign = -1; break;-----// 28
-----case ' ': goto hell;-----// fd
-----case '\n': goto hell;-----// 79
-----default: *n *= 10; *n += c - '0'; break;-----// c0
-----}-----// 2d
----}-----// c3
hell:-----// ba
```

```
----*n *= sign;-----// a0
}-----// 67
```

7.12. **128-bit Integer.** GCC has a 128-bit integer data type named `__int128`. Useful if doing multiplication of 64-bit integers, or something needing a little more than 64-bits to represent. There’s also `__float128`.

7.13. **Bit Hacks.**

```
int snoob(int x) {-----// 73
----int y = x & -x, z = x + y;-----// 12
----return z | ((x ^ z) >> 2) / y;-----// 97
}-----// 14

10. FORMULAS

- **Legendre symbol:** $\left(\frac{a}{b}\right) = a^{(b-1)/2} \pmod{b}$, b odd prime.
- **Heron’s formula:** A triangle with side lengths a, b, c has area $\sqrt{s(s-a)(s-b)(s-c)}$ where $s = \frac{a+b+c}{2}$.
- **Pick’s theorem:** A polygon on an integer grid strictly containing i lattice points and having b lattice points on the boundary has area $i + \frac{b}{2} - 1$. (Nothing similar in higher dimensions)
- **Euler’s totient:** The number of integers less than n that are coprime to n are $n \prod_{p|n} \left(1 - \frac{1}{p}\right)$ where each p is a distinct prime factor of n .
- **König’s theorem:** In any bipartite graph $G = (L \cup R, E)$, the number of edges in a maximum matching is equal to the number of vertices in a minimum vertex cover. Let U be the set of unmatched vertices in L , and Z be the set of vertices that are either in U or are connected to U by an alternating path. Then $K = (L \setminus Z) \cup (R \cap Z)$ is the minimum vertex cover.
- A minumum Steiner tree for n vertices requires at most $n - 2$ additional Steiner vertices.
- The number of vertices of a graph is equal to its minimum vertex cover number plus the size of a maximum independent set.
- **Lagrange polynomial** through points $(x_0, y_0), \dots, (x_k, y_k)$ is $L(x) = \sum_{j=0}^k y_j \prod_{\substack{0 \leq m \leq k \\ m \neq j}} \frac{x - x_m}{x_j - x_m}$
- **Hook length formula:** If λ is a Young diagram and $h_\lambda(i, j)$ is the hook-length of cell (i, j) , then then the number of Young tableaux $d_\lambda = n! / \prod h_\lambda(i, j)$.

- **Möbius inversion formula:** If $f(n) = \sum_{d|n} g(d)$, then $g(n) = \sum_{d|n} \mu(d) f(n/d)$. If $f(n) = \sum_{m=1}^n g(\lfloor n/m \rfloor)$, then $g(n) = \sum_{m=1}^n \mu(m) f(\lfloor \frac{n}{m} \rfloor)$.
- #primitive pythagorean triples with hypotenuse $< n$ approx $n/(2\pi)$.
- **Frobenius Number:** largest number which can’t be expressed as a linear combination of numbers a_1, \dots, a_n with non-negative coefficients. $g(a_1, a_2) = a_1 a_2 - a_1 - a_2$, $N(a_1, a_2) = (a_1 - 1)(a_2 - 1)/2$. $g(d \cdot a_1, d \cdot a_2, a_3) = d \cdot g(a_1, a_2, a_3) + a_3(d - 1)$. An integer $x > (\max_i a_i)^2$ can be expressed in such a way iff. $x \mid \gcd(a_1, \dots, a_n)$.

10.1. Physics.

- **Snell’s law:** $\frac{\sin \theta_1}{v_1} = \frac{\sin \theta_2}{v_2}$

10.2. **Markov Chains.** A Markov Chain can be represented as a weighted directed graph of states, where the weight of an edge represents the probability of transitioning over that edge in one timestep. Let $P^{(m)} = (p_{ij}^{(m)})$ be the probability matrix of transitioning from state i to state j in m timesteps, and note that $P^{(1)}$ is the adjacency matrix of the graph. **Chapman-Kolmogorov:** $p_{ij}^{(m+n)} = \sum_k p_{ik}^{(m)} p_{kj}^{(n)}$. It follows that $P^{(m+n)} = P^{(m)} P^{(n)}$ and $P^{(m)} = P^m$. If $p^{(0)}$ is the initial probability distribution (a vector), then $p^{(0)} P^{(m)}$ is the probability distribution after m timesteps.

The return times of a state i is $R_i = \{m \mid p_{ii}^{(m)} > 0\}$, and i is *aperiodic* if $\gcd(R_i) = 1$. A MC is aperiodic if any of its vertices is aperiodic. A MC is *irreducible* if the corresponding graph is strongly connected.

A distribution π is stationary if $\pi P = \pi$. If MC is irreducible then $\pi_i = 1/\mathbb{E}[T_i]$, where T_i is the expected time between two visits at i . π_j/π_i is the expected number of visits at j in between two consecutive visits at i . A MC is *ergodic* if $\lim_{m \rightarrow \infty} p^{(0)} P^m = \pi$. A MC is ergodic iff. it is irreducible and aperiodic.

A MC for a random walk in an undirected weighted graph (unweighted graph can be made weighted by adding 1-weights) has $p_{uv} = w_{uv} / \sum_x w_{ux}$. If the graph is connected, then $\pi_u = \sum_x w_{ux} / \sum_v \sum_x w_{vx}$. Such a random walk is aperiodic iff. the graph is not bipartite.

An *absorbing* MC is of the form $P = \begin{pmatrix} Q & R \\ 0 & I_r \end{pmatrix}$. Let $N = \sum_{m=0}^\infty Q^m = (I_t - Q)^{-1}$. Then, if starting in state i , the expected number of steps till absorption is the i -th entry in $N1$. If starting in state i , the probability of being absorbed in state j is the (i, j) -th entry of NR .

Many problems on MC can be formulated in terms of a system of recurrence relations, and then solved using Gaussian elimination.

10.3. **Burnside’s Lemma.** Let G be a finite group that acts on a set X . For each g in G let X^g denote the set of elements in X that

are fixed by g . Then the number of orbits

$$|X/G| = \frac{1}{|G|} \sum_{g \in G} |X^g|$$

10.4. **Bézout’s identity.** If (x, y) is any solution to $ax + by = d$ (e.g. found by the Extended Euclidean Algorithm), then all solutions are given by

$$\left(x + k \frac{b}{\gcd(a, b)}, y - k \frac{a}{\gcd(a, b)}\right)$$

10.5. Misc.

10.5.1. *Determinants and PM.*

$$\det(A) = \sum_{\sigma \in S_n} \text{sgn}(\sigma) \prod_{i=1}^n a_{i, \sigma(i)}$$

$$\text{perm}(A) = \sum_{\sigma \in S_n} \prod_{i=1}^n a_{i, \sigma(i)}$$

$$\begin{aligned} pf(A) &= \frac{1}{2^n n!} \sum_{\sigma \in S_{2n}} \text{sgn}(\sigma) \prod_{i=1}^n a_{\sigma(2i-1), \sigma(2i)} \\ &= \sum_{M \in \text{PM}(n)} \text{sgn}(M) \prod_{(i, j) \in M} a_{i, j} \end{aligned}$$

10.5.2. *BEST Theorem.* Count directed Eulerian cycles. Number of OST given by Kirchoff’s Theorem (remove r/c with root) $\# \text{OST}(G, r) \cdot \prod_v (d_v - 1)!$

10.5.3. *Primitive Roots.* Only exists when n is $2, 4, p^k, 2p^k$, where p odd prime. Assume n prime. Number of primitive roots $\phi(\phi(n))$ Let g be primitive root. All primitive roots are of the form g^k where $k, \phi(p)$ are coprime.

k -roots: $g^{i \cdot \phi(n)/k}$ for $0 \leq i < k$

10.5.4. *Sum of primes.* For any multiplicative f :

$$S(n, p) = S(n, p - 1) - f(p) \cdot (S(n/p, p - 1) - S(p - 1, p - 1))$$

10.5.5. *Floor.*

$$\begin{aligned} \lfloor \lfloor x/y \rfloor / z \rfloor &= \lfloor x/(yz) \rfloor \\ x \% y &= x - y \lfloor x/y \rfloor \end{aligned}$$
